01 • Content and process theories of motivation

(1) Content theories say motivation comes from which needs are unmet, while process theories say it comes from how people reason about effort, reward and fairness.
One-sentence model • ●●

(2) Does not claim the needs are universal or innate
McClelland • What it does NOT claim • ●●●

(3) Treating the two factors as opposite ends of one scale
Herzberg • Exam trap • ●●●

(4) Does not treat the terms as additive
Vroom • What it does NOT claim • ●●●

(5) Scenarios showing regression point to ERG, not Maslow
Maslow • Exam trap • ●●●

(6) Does not predict from absolute reward level alone
Adams • What it does NOT claim • ●●●

(7) Does not allow moving back down the hierarchy
Maslow • What it does NOT claim • ●●●

(8) Process
Vroom • Family • ●●

(9) Does not require needs to be met in order
Alderfer • What it does NOT claim • ●●●

(10) Process
Adams • Family • ●●

(11) Described as innate rather than acquired
McClelland • Exam trap • ●●●

(12) Content
Herzberg • Family • ●●

(13) Chosen only when regression is described; otherwise Maslow
Alderfer • Exam trap • ●●●

(14) Additive phrasing in the stem makes the option wrong
Vroom • Exam trap • ●●●

(15) Confused with expectancy when a reward is mentioned at all
Adams • Exam trap • ●●●

(16) Whether the theory names the contents of motivation (which needs) or the reasoning that produces it (how the person evaluates effort and reward). Content theories answer "what", process theories answer "how".
Decisive distinction • ●●●

(17) Any description of moving *back down* after frustration is ERG. Maslow forbids it.
Maslow / Alderfer (ERG) • ●●●

(18) If removing it causes complaints but adding it causes nothing, it is hygiene.
Herzberg hygiene / Herzberg motivator • ●●●

(19) A comparison with another person is Adams. A judgement about one's own effort chain is Vroom.
Vroom / Adams • ●●●

(20) It removes dissatisfaction; motivation requires achievement, recognition, responsibility
Improving pay and working conditions will increase motivation. • ●●●

(21) Not for ERG, which permits simultaneous activation and regression
A person must satisfy lower needs before higher ones become active. • ●●●

(22) Expectancy is multiplicative — zero expectancy gives zero motivation
High valence alone produces high motivation. • ●●●

02 • Reliability and validity

(23) Reliability is consistency of measurement and validity is whether the thing measured is the thing intended; a test can be perfectly reliable and completely invalid, but never valid without being reliable.
One-sentence model • ●●

(24) Confused with face validity, which is about appearance only
Content validity • Exam trap • ●●●

(25) Expecting a single number — it is a body of evidence
Construct validity • Exam trap • ●●●

(26) Predictive and concurrent differ only in timing
Criterion validity • Exam trap • ●●●

(27) A poorly defined construct
Construct validity • Main threat • ●●●

(28) Alpha rises with test length even without improvement
Internal consistency • Main threat • ●●●

(29) An incomplete domain specification
Content validity • Main threat • ●●●

(30) Confused with parallel-forms reliability
Inter-rater reliability • Exam trap • ●●●

(31) Rater drift over a long scoring session
Inter-rater reliability • Main threat • ●●●

(32) Practice and memory effects inflate it
Test-retest reliability • Main threat • ●●●

(33) Range restriction attenuates the coefficient
Criterion validity • Main threat • ●●●

(34) Do the items hang together?
Internal consistency • Question it answers • ●●

(35) Reliability asks whether repeated measurement agrees with itself. Validity asks whether it agrees with reality. Only validity requires anything outside the test.
Decisive distinction • ●●●

(36) If the evidence comes from inside the test alone, it is reliability.
Reliability / Validity • ●●●

(37) Face validity is judged by the test-taker; content validity by experts against a specification.
Face validity / Content validity • ●●●

(38) A reliable test can measure the wrong construct with perfect consistency
A highly reliable test is a good test. • ●●●

(39) Very high alpha can indicate redundant items rather than quality
Cronbach's alpha above 0.9 indicates an excellent scale. • ●●●
